1. INTRODUCTION:

Effects of economic recession on life satisfaction

Economic crises are often characterized as periods of rising unemployment and inflation as well as decreasing material well-being. Not surprisingly, the most recent economic crisis in Europe has accompanied considerable losses in life satisfaction, particularly in several Mediterranean countries (Veenhoven, 2013) in which regional unemployment rates rose as high as 35%.

The negative relationship between unemployment and subjective well-being is well documented in the economic literature and is explained by income loss and by the psychic costs of joblessness related to identity problems, psychological distress and low self-esteem (Veenhoven and Hagenaars, 1989; Gallie and Russell, 1998). However, economic crises also tend to affect the subjective well-being of those who manage to keep their jobs (Di Tella et al., 2003). As noted by Frey (2007), this phenomenon can be explained not only by the effect of economic crises on crime, public expenditures and income inequality but also by their effect on the financial distress of households. This financial distress can originate from the need to support unemployed family members, increased inflation, reduced average well-being and career prospects (Blanchflower and Oswald, 1994), longer working hours without overtime compensation (Stewart and Swaffield, 1997) and increased fear of becoming unemployed in the near future and losing material well-being (Luechinger et al., 2010). There is a growing body of literature on the relationship between job insecurity and subjective well-being in times of crisis (e.g., Clark et al., 2010; Luechinger et al., 2010; Green, 2011), but there is relatively little empirical evidence on how financial distress moderates the relationship between macroeconomic conditions and the life satisfaction of employees (for an exception, see Gudmundsdottir, 2013). It can be expected that the more an employee is attached to and reliant on his job to make ends meet, the higher the fear of losing this job and the more that worsening macroeconomic conditions negatively affect the employee's life satisfaction. Employees who are highly dependent on their jobs typically include blue-collar workers (Naswall and De Witte, 2003) and employees with lower education or in low-skilled occupations (Fugate et al., 2004). These groups have the lowest-paying jobs and a lower degree of employability or substantially lower chances to find alternative employment (Sverke et al., 2004).

2. ECONOMETRIC FRAMEWORK

To examine the relationships among financial distress, macroeconomic conditions and life satisfaction, we specify a simple reduced-form life satisfaction model (see also Di Tella et al., 2003; Frey et al., 2009): vector of time dummies included to capture global time-related external shocks and j is a residual error.

3. DATA

Annual data on life satisfaction and personal characteristic variables for employees in the EU-28 (excluding Malta) and Iceland are taken from the Eurobarometer Survey Series. Overall, our sample consists of approximately 50 000 observations between 2008 and 2012.

Subjective well-being is measured using a 4-point scale measure of life satisfaction on the following question: 'On the whole, are you very satisfied, fairly satisfied, not very satisfied, or not at all satisfied with the life you lead?'. Possible answers are (1) not at all satisfied, (2) not satisfied, (3) fairly satisfied and (4) very satisfied.

To capture an employee's financial distress, we include variables related to the financial situation of the household and the future financial expectations of the household. The financial situation of the household corresponds to the following question: 'How would you judge the current financial situation of your household?'. Respondents choose between 'very bad', 'rather

bad', 'rather good' and 'very good'. Likewise, our measure of financial expectations is measured by a self-report measure asking 'What are your expectations for the next twelve months: will the next twelve months be "better", "worse", or the "same", when it comes to the financial situation of your household?'

Other personal characteristics included in the analysis are related to gender, age, marital status, household composition, education and occupation type.³ With respect to macroeconomic conditions, we include variables related to the unemployment rate, GDP per capita and inflation. Data on the unemployment rate are measured at the regional level (NUTS- 2) and obtained from Eurostat. Information on GDP per capita and inflation rates (consumer prices) are measured at the national level and obtained from the World Bank Development Indicators.⁴ An overview where LS_{jit} is a self-report measure of life satisfaction for individual j in region i in year t , $Financial\ Distress_{jit}$ is a vector of self-report measures of financial distress, $Macro_{it}$ is a vector of macroeconomic characteristics in region i in year t , $Personal_{jit}$ is a vector of other personal characteristics of the employees, e_i is a vector of region (NUTS-2)¹ dummies² to control for time-invariant regional characteristics, X_t is a vector of all variables included in the analysis and descriptive statistics are provided in [Appendices 1](#) and [2](#), respectively.

$$LS_{jit} = \Theta Macro_{it} + \Omega Financial\ Distress_{jit} + \sum Personal_{jit} + \varepsilon_i + \lambda_t + \mu_{jit}$$

4. EMPIRICAL RESULTS

Given the categorical nature of our dependent variable LS_{jit} , all models were estimated using ordered probit regressions.⁵ [Table 1](#) presents the results using the full sample of employees. Financial distress is negatively associated with life satisfaction (column (1)). Compared to employees who are in a good to very good financial situation, employees who are in a bad or very bad financial situation are less satisfied. Likewise, employees who expect that the future financial situation of their household will worsen are generally less happy than employees who expect that the future financial situation of their household will improve or remain the same (column (2)). Turning to the effects of macroeconomic conditions on life satisfaction ([Table 1](#), columns (3) and (4)), we find that the regional unemployment rate and inflation are negatively associated with the life satisfaction of employees. By contrast, we find no significant correlation between GDP per capita and individual life satisfaction.

[Tables 2](#) and [3](#) examine the hypothesis that the relationship between macroeconomic conditions and life satisfaction is contingent on the financial distress levels of employees. Here, we partition the sample by (1) the financial situation of the household and (2) the financial expectations of the household. [Table 2](#) presents the results by the financial situation of the household. Although we find evidence of a strong negative association between the regional unemployment rate and life satisfaction for employees in a very bad financial situation, the regional unemployment rate is not correlated with the life satisfaction of employees in a very good financial situation. The regional unemployment rate is also negatively associated with the life satisfaction of employees who are in a rather good or rather bad financial situation, but these

groups seem to be less deterred by increasing unemployment rates. Similar results are found with regard to inflation, whereas the effect of GDP per capita does not seem to vary by the financial situation of the household. **Table 3** shows the results for the different groups delimited by expectations regarding the financial situation of the household. The results support the notion that the responsiveness of life satisfaction to macroeconomic conditions differs between the three groupings. Whereas regional unemployment and inflation are negatively correlated with the life satisfaction of employees who expect that the financial situation of their household will worsen in the near future, regional unemployment and inflation are not associated with the life satisfaction of employees who expect that the financial situation of their household will improve.⁶

The reported differences between the different groups are not only statistically significant but also meaningful from a substantive point of view. **Table 4** shows the percentage point change for those who become unhappy (not at all satisfied or not satisfied) by changes in the regional unemployment rate. In line with expectations, it appears that a 5-percentage-point increase in the regional unemployment rate would increase the percentage of unhappy employees who are in a bad financial situation by 6.4 percentage points. An equal increase in the regional unemployment rate would increase the group of unhappy employees in a rather good financial situation by only 1.1 percentage points. Similar conclusions can be drawn when comparing employees by expectations.

5. DISCUSSION AND CONCLUSION

Employees who are in financial distress are negatively affected by rising unemployment and inflation, but financially safe employees are not. Because employees in financial distress can be disproportionately found in groups that are already generally less satisfied with life (i.e., lower-educated, low-skilled, blue-collar workers), economic crises can increase inequality in subjective well-being. This finding should be further examined in future research.

Such an effect should be interpreted with caution. The indicators regarding the measurement of financial distress (financial situation of the household and future expectations) are subjective. It is possible that individuals change their reference point when their evaluation of financial matters is performed during recession periods. Decreased life satisfaction during recessions cannot be justified only by financial difficulties. Future research could address whether other social and economic conditions, such as increased crime, reduced public expenditures or income inequality (Frey, 2007), moderate the relationship between crisis and life satisfaction.

NOTES

¹The Nomenclature of Territorial Units for Statistics (NUTS) classification is a geocode standard to subdivide the economic territory of the European Union. NUTS-2 regions are basic regions for application of regional policies and normally have a population of 800 000 to 3 million.

²The dummy controls for 205 European regions for which coefficients were found to be significant.

³Type of occupation distinguishes between blue-collar versus white-collar labour and low-skilled versus high-skilled occupations according to 'Eurostat's Adult Education Survey.

⁴Unfortunately, there were no recent GDP per capita and inflation data available at the regional level.

⁵ A challenge here is that unhappiness and financial distress often go hand in hand and may, in fact, aggravate each other. Moreover, there is a possibility of reverse causality, with increasing unhappiness exacerbating financial distress. One solution to this problem would be to instrument financial distress, but finding credible instruments is difficult. Instead, we recognize this problem and caution that our results should be interpreted as conditional associations rather than reflecting causal relationships.

⁶The negative and significant correlation for GDP per capita in the regression for employees who expect that the financial situation of their household will worsen may be explained by social comparison effects and requires further examination.
